For iris flower classification using Machine Learning, the dataset from Scikit-learn library is loaded using Seaborn

```
import seaborn as sns
```

```
a=sns.load_dataset('iris')
```

```
a.head(3)
```

	sepal_length	sepal_width	petal_length	petal_width	species
0	5.1	3.5	1.4	0.2	setosa
1	4.9	3.0	1.4	0.2	setosa
2	4.7	3.2	1.3	0.2	setosa

```
a.tail(3)
```

	sepal_length	sepal_width	petal_length	petal_width	species
147	6.5	3.0	5.2	2.0	virginica
148	6.2	3.4	5.4	2.3	virginica
149	5.9	3.0	5.1	1.8	virginica

Checking for null values

```
a.info() # implies the absence of null values in the dataset
```

```
<class 'pandas.core.frame.DataFrame'>
RangeIndex: 150 entries, 0 to 149
Data columns (total 5 columns):
 #   Column        Non-Null Count  Dtype
---  ------        --------------  -----
 0   sepal_length  150 non-null    float64
 1   sepal_width   150 non-null    float64
 2   petal_length  150 non-null    float64
 3   petal_width   150 non-null    float64
 4   species       150 non-null    object
dtypes: float64(4), object(1)
memory usage: 6.0+ KB
```

Checking for duplicates
```
a.duplicated() # no duplicates
```

```
0      False
1      False
2      False
3      False
4      False
       ...
145    False
146    False
147    False
148    False
149    False
Length: 150, dtype: bool
```
EDA

```
sns.scatterplot(data=a,x='sepal_length',y='petal_length',hue='species')
```
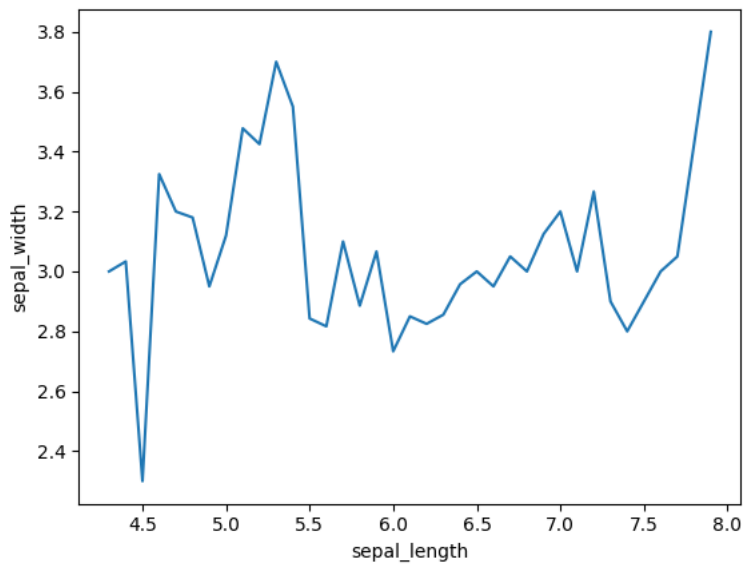

```
<Axes: xlabel='sepal_length', ylabel='petal_length'>
```

```
sns.histplot(data=a['sepal_length'],bins=3)
```

```
<Axes: xlabel='sepal_length', ylabel='Count'>
```

```
sns.lineplot(data=a,x='sepal_length',y='sepal_width',errorbar=None)
```

```
<Axes: xlabel='sepal_length', ylabel='sepal_width'>
```

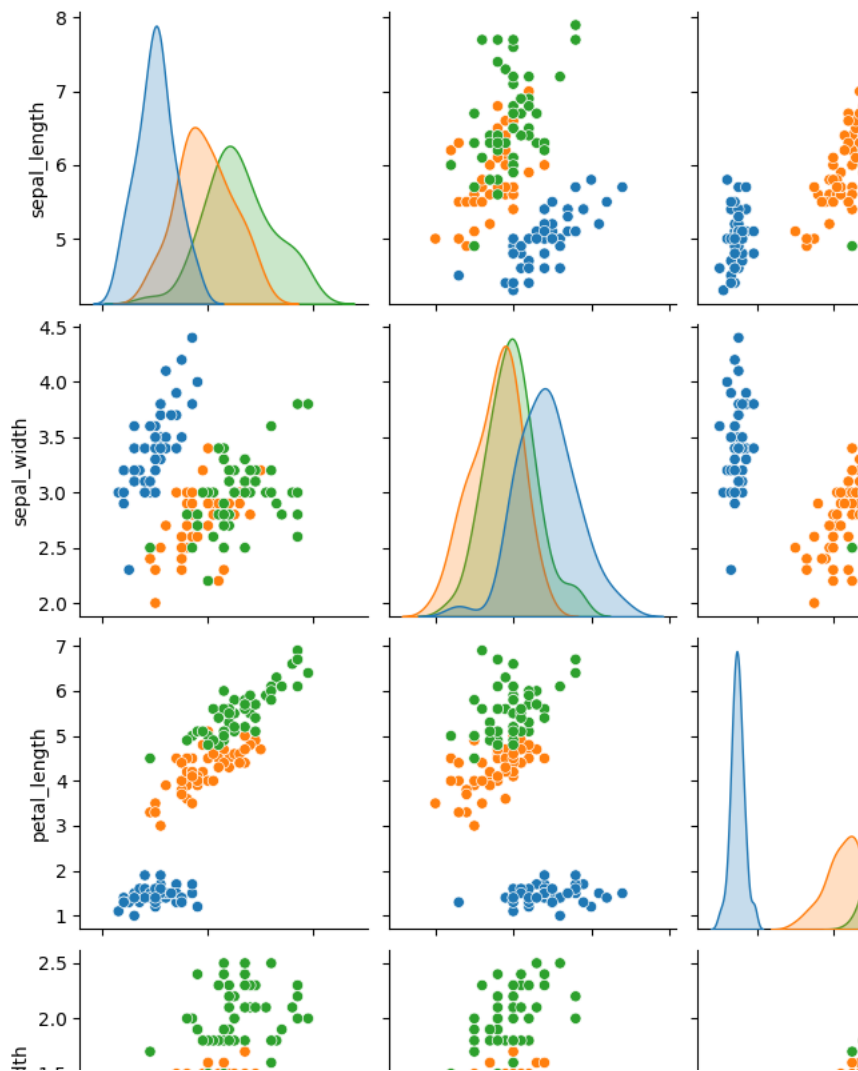

Pairplot is created to view the relationship between each of the variable with others present in the data.

```
sns.pairplot(data=a,hue='species')
```
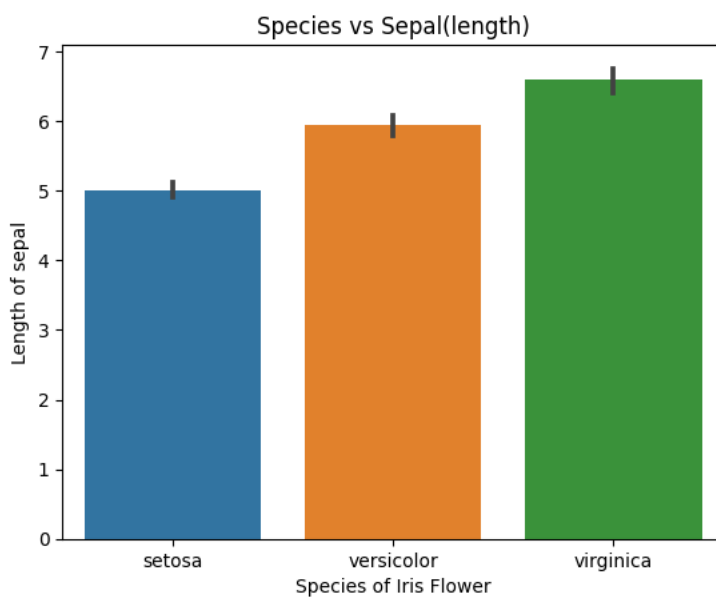

```
<seaborn.axisgrid.PairGrid at 0x78aafdec3700>
```

Data based on each species

```python
import matplotlib.pyplot as plt

sns.barplot(data=a,x='species',y='sepal_length') # Virginica is the species with highest sepal length
plt.xlabel('Species of Iris Flower')
plt.ylabel('Length of sepal')
plt.title("Species vs Sepal(length)")
plt.show()
```
```
sns.barplot(data=a,x='species',y='petal_length')# Virginica is the species with highest petal length
plt.xlabel('Species of Iris Flower')
plt.ylabel('Length of Petal')
plt.title("Species vs Petal(length)")
plt.show()
```

```
sns.barplot(data=a,x='species',y='sepal_width') # Setosa is the species with highest sepal width
plt.xlabel('Species of Iris Flower')
plt.ylabel('Width of sepal')
plt.title("Species vs Sepal(width)")
plt.show()
```

```
sns.barplot(data=a,x='species',y='petal_width') # Virginica is the species with highest petal width
plt.xlabel('Species of Iris Flower')
plt.ylabel('Width of petal')
plt.title("Species vs Petal(width)")
plt.show()
```
Species vs Petal(width)
From above 4 graphs, we can conclude that the species Virginica is higher in terms of size.

Machine Learning

Splitting the data into input and output

```
x=a.drop(columns='species') # x- input
y=a['species'] # y - output
```

Since, the data has to be classified use of categorical value is to be noted. So, to make easier, the 3 classes are converted into numerics.i.e, 'setosa'=1, 'versicolor'=2, 'virginica'=3.

```
y=y.replace({'setosa':1, 'versicolor':2, 'virginica':3})
```

Standardising the input data

```
from sklearn.preprocessing import StandardScaler
```

```
std=StandardScaler()
```

```
import pandas as pd
```

```
x=pd.DataFrame(data=std.fit_transform(x),columns=x.columns)
```

Data gets divided into training and testing data

```
from sklearn.model_selection import train_test_split
```

```
x_train,x_test,y_train,y_test=train_test_split(x,y,test_size=0.2)
```

As, the data is composed of multi class variable, 2 algorithms are used for model training - (1) K Nearest Classification; (2) Random Forests

(1) K Nearest Classification

```
from sklearn.neighbors import KNeighborsClassifier
```

```
kc=KNeighborsClassifier(n_neighbors=2) # defining a model
```

```
kc.fit(x_train,y_train) # training the model
```

```
▼        KNeighborsClassifier
KNeighborsClassifier(n_neighbors=2)
```

```
kc.score(x_test,y_test) # testing the model
```

```
    1.0
```

```
kc_a=KNeighborsClassifier(n_neighbors=5) # same model with increased number of neighbors
kc_a.fit(x_train,y_train)# training
kc_a.score(x_test,y_test) # testing the score
```

```
    1.0
```

(2) Random Forests

```
from sklearn.ensemble import RandomForestClassifier
```

```
rfc=RandomForestClassifier(n_estimators=10) # building the model
```

```
rfc.fit(x_train,y_train)# training the model
```

```
          ▾         RandomForestClassifier
    RandomForestClassifier(n_estimators=10)
```

```
rfc.score(x_test,y_test)# testing
```

```
    1.0
```

```
rfc_a=RandomForestClassifier(n_estimators=50)
rfc_a.fit(x_train,y_train)
rfc_a.score(x_test,y_test)
```

```
    0.9666666666666667
```

By comparing (1) and (2), KNeighborsClassification is selected for flower iris classification which gained a better score than the other algorithm.
